- Data Collection and Preparation
- Feature Engineering
- Model Selection and Training
- Validation and Evaluation
- Deployment and Monitoring

Each step influences the effectiveness of the modeling techniques chosen. Our focus here is on the algorithms and methodologies that underpin the modeling phase.

Categories of Modeling Techniques in Predictive Analytics

In this review, we will primarily focus on regression, classification, ensemble, and some advanced techniques, as they form the backbone of most predictive analytics applications.

Regression Techniques

Regression models are used when the target variable is continuous. They estimate the relationship between the dependent variable and one or more independent variables.

Linear Regression

Principle: Assumes a linear relationship between input features and the output variable.

Equation:

$$\hat{y} = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_n x_n + \epsilon$$

Applications:

Limitations:

- Assumes linearity, which may not hold in complex real-world data
- Sensitive to outliers
- Multicollinearity issues

Polynomial Regression

Principle: Extends linear regression by adding polynomial terms to model non-linear relationships.

Use Case: When the relationship between variables is non-linear but can be approximated with polynomial functions.

Limitations:

- Risk of overfitting
- Increased computational complexity

Regularized Regression Techniques

To address overfitting and multicollinearity, regularization methods are employed:

- Ridge Regression: Adds L2 penalty to shrink coefficients
- Lasso Regression: Adds L1 penalty for feature selection
- Elastic Net: Combines L1 and L2 penalties

Applications: Variable selection and robust modeling in high-dimensional data.

Classification Techniques

Classification models predict categorical outcomes, such as yes/no, spam/not spam, or customer churn/no churn.

Logistic Regression

Principle: Models the probability that an input belongs to a particular class using the logistic function.

Equation:

$$P(y=1|X) = \frac{1}{1 + e^{-(\beta_0 + \beta_1 x_1 + \dots + \beta_n x_n)}}$$

Applications:
